

# Apollo practical 1

$x!$  Stephane Hess

[stephane.hess@gmail.com](mailto:stephane.hess@gmail.com)

$$\Gamma(n + \frac{1}{2}) = \frac{\sqrt{\pi}}{2^n} (2n - 1)!!$$

$$\frac{1}{\sqrt{1 - k^2 \sin^2(x)}} = 1 + \sum_{n=1}^{\infty} \sum_{k=1}^{n-1}$$

$$y = \int_0^x e^{-\frac{(x-t)^2}{2}} dt$$

$$\frac{p}{(x-a)^2 + b^2} n$$

$$\sigma_x = \sqrt{\frac{\sum_{i=1}^n (x_i - \bar{x})^2}{n}}$$

$$\sum_{i=1}^n (x_i - \bar{x})^2$$

$$\int f^2(x) dx$$

$$\sigma_x$$

# Apollo practical 1

## Outline

---

- 1 An introduction to *Apollo*
- 2 First model in *Apollo*
- 3 Changes to a model: adding explanatory variables
- 4 Mode specific time coefficients
- 5 WTP space

# An introduction to Apollo

# An introduction to *Apollo*

## Software for estimation

- Model estimation is the key step in any choice study
- Users rely on software for this
- Several options exist, with big differences in capabilities

# An introduction to Apollo

## Choice modelling: history

- Used across different disciplines for over four decades
- Initially, small number of (advanced) users
- Similarly, small number of software packages
- Explosion in number of users and fields since 1990s
- Ever broader group of users access to ever more advanced models

# An introduction to Apollo

## Choice modelling: software split

- Fragmentation of community in terms of software, also along discipline lines
- Advanced users develop their own code
- Others split between commercial software and freeware tools
  - Commercial packages generally more powerful but with limitations in terms of available model structures or possibility for customisation
  - Freeware packages may have limitations in performance but benefit from more regular developments to accommodate new model structures

# An introduction to *Apollo*

## ALogit

- Commercial software package
- By far the fastest package
- Can work with many 1,000s of alternatives and very large samples
- Widely used solution for large scale modelling
- Limited set of model structures, and restrictions on flexibility for model specification
- Limited ability for user to code models
- Classical estimation only
- Windows only

[www.alogit.com](http://www.alogit.com)

# An introduction to *Apollo*

## Biogeme

- Free package, runs using Python
- Very powerful and flexible
- Large user base
- Runs on Windows and MacOS
- Classical estimation only
- Requires some Python knowledge

BIOGEME

<https://biogeme.epfl.ch/>

# An introduction to Apollo

## NLogit

- Commercial software package
- Powerful solution for applied modelling
- Includes graphical interface
- Limited ability for user to code models
- Classical estimation only
- Windows only

<https://www.limdep.com/>

# An introduction to Apollo

## Other packages

- ❑ ALogit, Biogeme and NLogit are longstanding packages developed by leading choice modellers
- ❑ Also many smaller packages in Matlab, Python, R and Stata
- ❑ Generally focus on just a small number of features
- ❑ Big differences in flexibility, speed and accessibility
- ❑ Incomplete list of examples
  - Matlab: DCE, Kenneth Train's code
  - R: mixl, RSGHB
  - Python: Pylogit
  - Stata: bayesmlogit, clogit, gmnl, mixlogit

# An introduction to *Apollo*

## Black boxes are a problem!

- Many packages are black box tools
- User has little or no knowledge of what goes on “under the hood”
- Has made advanced models accessible to a broader group of users
- Disconnect between theory and software increases risk of misinterpretations and misspecifications
- Can also hide relevant nuances of modelling process and mistakenly give the impression that choice models are “easy tools” to use

# An introduction to *Apollo*

## Bayesians vs the rest

- Existing software almost exclusively allows use of only either classical estimation techniques or Bayesian techniques
- Fragmentation again runs largely in parallel with discipline boundaries
- Has only served to further contribute to lack of interaction/dialogue between classical and Bayesian communities

# An introduction to Apollo

## Existing limitations led to development of Apollo

- ❑ Culmination of 20 years of work
- ❑ Started with Ox code developed by Hess at Imperial College, translated into R at University of Leeds
- ❑ Combined with code developed by Palma at Pontificia Universidad Católica de Chile
- ❑ Major continuous further developments

- ❑ Couldn't base name on single model family as *Apollo* is more general
- ❑ Failure to come up with clever acronym led us to Greek mythology
- ❑ *Apollo* was the Greek god of prophecy

# An introduction to *Apollo*

## Approach in *Apollo*

**Free access:** *Apollo* is a completely free package which does not rely on commercial statistical software as a host environment.

**Big community:** *Apollo* relies on R, a free software environment for statistical computing and graphics, which is very widely used across disciplines and works well across different operating systems.

**Transparent, yet accessible:** *Apollo* is neither a blackbox nor does it require expert econometric skills. The user can see as much or as little detail of the underlying methodology as desired, but the link between inputs and outputs remains.

**Ease of use:** *Apollo* combines easy to use R functions with new intuitive functions without unnecessary jargon or complexity.

# An introduction to *Apollo*

## Approach in *Apollo*

**Modular nature:** *Apollo* uses the same code structure independently of whether the simplest multinomial logit model is to be estimated, or a complex structure using random coefficients and combining multiple model components.

**Fully customisable:** *Apollo* provides functions for many well known models but the user is able to add new structures and still make use of the overall code framework. This for example extends to coding expectation-maximisation routines.

**Discrete and continuous:** *Apollo* incorporates functions not just for commonly used discrete choice models but also for a family of models that looks jointly at discrete and continuous choices.

# An introduction to *Apollo*

## Approach in *Apollo*

**Novel structures:** *Apollo* goes beyond standard choice models by incorporating the ability to estimate Decision Field Theory (DFT) models, a popular accumulator model from mathematical psychology.

**Classical and Bayesian:** *Apollo* does not restrict the user to either classical or Bayesian estimation but easily allows changing from one to the other.

**Easy multi-threading:** *Apollo* allows users to split the computational work across multiple processors without making changes to the model code.

**Not limited to estimation:** *Apollo* provides a number of pre and post-estimation tools, including diagnostics as well as prediction/forecasting capabilities and posterior analysis of model estimates.

# An introduction to Apollo

Resources: [www.apollochoicemodelling.com](http://www.apollochoicemodelling.com)

The screenshot shows the homepage of the Apollo website. At the top left is the Apollo logo, which consists of a stylized 'A' icon followed by the word 'Apollo'. The top right features a dark navigation bar with white text containing links for HOME, CODE, MANUAL, EXAMPLES, FAQ, and FORUM. Below the navigation bar, there are several sections: 'CODE & NEW FEATURES' showing a snippet of R code; 'MANUAL & PAPER' showing a stack of papers; 'EXAMPLES & DATA' showing a grid of blue spheres with 'R' icons; 'FREQUENT QUESTIONS' showing a wooden board with 'FAQ' letters; and 'FORUM' showing two people working at a desk. At the bottom, there are footer links for choice modelling centre, Journal of CHOICE Modelling, ICMC, and a Twitter link.

# An introduction to *Apollo*

## Documentation

- ❑ Website includes a detailed manual and shorter research paper
- ❑ In addition, syntax help for all functions is available directly in R
  - e.g. `?apollo_mnl`

R: Calculates Multinomial Logit probabilities - File in Tree

Documentation

**Calculates Multinomial Logit probabilities**

**Description**

Calculates the probabilities of a Multinomial Logit model and can also perform other operations based on the value of the `functionality` argument.

**Usage**

```
apollo_mnl(mnl_settings, functionality)
```

**Arguments**

`mnl_settings` List of inputs of the MNL model. It should contain the following.

- `alternatives`: Named numeric vector. Names of alternatives and their corresponding value in `choiceVec`.
- `avail`: Named list of numeric vectors or scalars. Availabilities of alternatives, one element per alternative. Names of elements must match those in `alternatives`. Values can be 0 or 1. These can be scalars or vectors (of length equal to rows in the database). A user can also specify `avail=1` to indicate universal availability, or omit the setting completely.
- `utilities`: Named numeric vector. Contains choices for all observations. It will usually be a column from the database. Values are defined in `alternatives`.
- `utilities`: Named list of deterministic utilities. Utilities of the alternatives. Names of elements must match those in `alternatives`.
- `rows`: Boolean vector. Consideration of which rows to include. Length equal to the number of observations (`nObs`), with entries equal to TRUE for rows to include, and FALSE for rows to exclude. Default is "all", equivalent to `rep(TRUE, nObs)`. Set to "all" by default if omitted.
- `componentName`: Character. Name given to model component. If not provided by the user, Apollo will set the name automatically according to the element in `y` to which the function output is directed.

`functionality` Character. Setting instructing Apollo what processing to apply to the likelihood function. This is in general controlled by the functions that call `apollo_getLikelihood`, though the user can also call `apollo_getProbabilities` manually with a given functionality for testing/debugging. Possible values are:

- `"component"`: For further processing/debugging, produces likelihood for each model component (if multiple components are present) at the level of individual draws and observations.
- `"model"`: For model, produces likelihood of the full model, at the level of individual inter-individual draws.
- `"exitless"`: For model estimation, produces likelihood of the full model, at the level of individual decision-makers, after averaging across draws.
- `"gradient"`: For model estimation, produces analytical gradients of the likelihood, where possible.
- `"export"`: Prepares output for post-estimation reporting.
- `"prediction"`: For model prediction, produces probabilities for individual alternatives and individual model components (if multiple components are present) at the level of an observation, after averaging across draws.
- `"preprocess"`: Prepares likelihood functions for use in estimation.
- `"raw"`: For debugging, produces overall model likelihood with constants only.
- `"export_tt"`: Prepares output summarising model and choiceSet structure.
- `"validate"`: Validates model specification, produces likelihood of the full model, at the level of individual decision-makers, after averaging across draws.
- `"zero_tt"`: Produces overall model likelihood with all parameters at zero.

# An introduction to *Apollo*

## Why R?

---

- Very powerful open source package
- Large number of packages available for econometric and statistical analysis
- Allows user to take the outputs from the choice model and process them directly into further output

# An introduction to Apollo

## Installing and updating *Apollo*

How do I install *Apollo*? enter `install.packages("apollo")` in R console

How do I update *Apollo*? You update *Apollo* by re-installing it

Error during installation that package not available for the R version I am running?

Update R to the latest version and re-install *Apollo*

Why does it not work on my company laptop/desktop computer Often computers from big organisations will install R packages in shared libraries. As a general recommendation, always install packages in local libraries, i.e. in a folder in the local hard drive. You can see your active libraries by typing `.libPaths()`. This will list the active libraries. If the local library is, for example, the second one in the list, you should keep only that one by typing `.libPaths(.libPaths()[2])`. Then you should try installing *Apollo* again.

# An introduction to *Apollo*

## Files required

- A data file (various formats can be read into R)
  - not needed if data is read from a package
- A model file
  - contains all details on the model and tells R what routines to run
- Easier if data and model files are in the same directory

# An introduction to *Apollo*

## Data format

- *Apollo* uses “wide” format
- All necessary information to calculate likelihood of a single observation should be contained in a single row of the data
- In more practical terms, for an MNL model, this means that attributes for all alternatives should be contained in each row
- Most common format in choice modelling, uses less space, and more general in allowing for a mixture of different dependent variables in the same data
- Some other software uses “long” format, with one row per alternative
  - *Apollo* is not set up for such data, but reshaping the data is a straightforward task using `apollo_longToWide`

# An introduction to Apollo

## A language and an interface

- R is a command line language
- Various shells exist to run R in
- This allows the user to have a script visible, which can then be run line by line or altogether
- We use RStudio
- Need to make sure to open your .R model files in RStudio, not directly in R

# An introduction to Apollo

## RStudio windows

Window showing script (from where we select and run code)

```

# First model in *Apollo*

# First model in Apollo

## Data from package: `apollo_modeChoiceData`

- Mode choice dataset, with four alternatives (car, bus, air, rail)
- 2 revealed preference choices per person
- Followed by 14 stated preference choices
- Travel time and cost for all, plus access time for non-car options
- Also a service quality attribute for air and rail in the SP data (1=no frills, 2=wifi, 3=food)
- 500 people, giving us 1,000 RP observations and 7,000 SP observations
- Not all modes available for all individuals
- Respondent characteristics: income, gender, purpose (business *vs* leisure)

# First model in *Apollo*

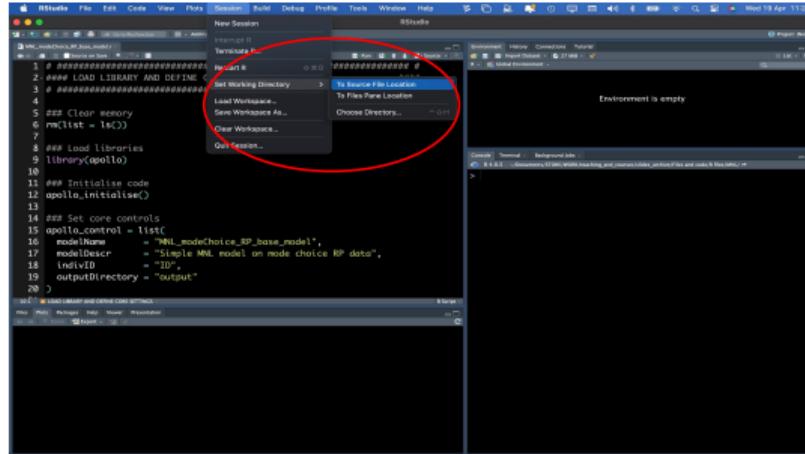

## Start with a simple model

- ❑ Should always start with a base model
- ❑ No interactions, just main effects
- ❑ Shows us that the data works, and an important starting point for model comparison

# First model in Apollo

R file: MNL\_modeChoice\_RP\_base\_model.r

- First we need to set our working directory

# First model in Apollo

Visible in history, console and files panel

The screenshot shows the RStudio interface with three main panels highlighted by red circles:

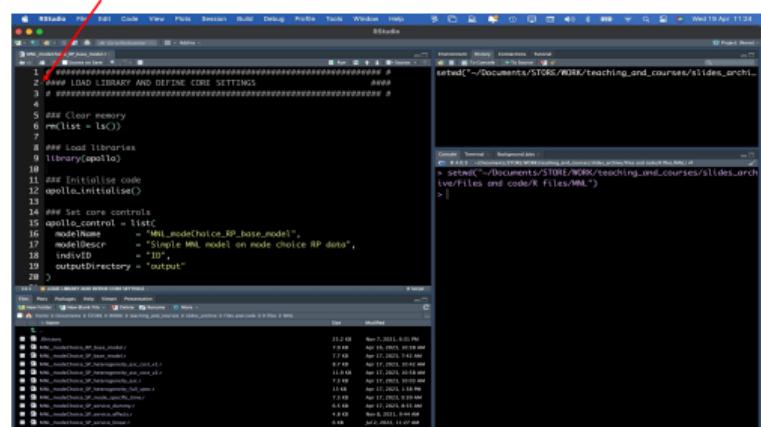

- Console Panel:** Shows the command `setwd("~/Documents/STORE/WORK/teaching_and_courses/slides_archive/Files and code/R files/MNL")` being run.
- History Panel:** Shows the command `setwd("~/Documents/STORE/WORK/teaching_and_courses/slides_archive/Files and code/R files/MNL")` listed along with other recent commands.
- Files Panel:** Shows the file structure of the MNL folder, including files like `MNL.Rnw`, `MNL_modeChoice_RP_base_model.r`, and various `.tex` and `.aux` files.

```
## LOAD LIBRARY AND DEFINE CORE SETTINGS
## Clear memory
rm(list = ls())
## Load libraries
library(Apollo)
## Initialise code
apollo initialise()
## Set core controls
apollo_control = list(
  modelName = "MNL_modeChoice_RP_base_model",
  modelDescr = "Simple MNL model on mode choice RP data",
  indivID = "ID",
  outputDirectory = "output"
)
## LOAD LIBRARY AND DEFINE CORE SETTINGS
## Clear memory
rm(list = ls())
## Load libraries
library(Apollo)
## Initialise code
apollo initialise()
## Set core controls
apollo_control = list(

  indivID = "ID",
  outputDirectory = "output"
)
```

# First model in Apollo

## R syntax

- A line beginning with a # is a comment
- We use ### to indicate a comment, and lines starting with a single # are lines that a user can turn on/off
- Lines ending in ##### or ---- are section headings
- Can collapse code into section headings by clicking on downwards arrow in margin

The screenshot shows an RStudio interface with a code editor containing R code. A red arrow points to the first line of the code, which is a comment starting with '#'. The code defines a model structure, including library imports, memory clearing, and model initialization. It also sets core controls like mode choice and output directory.

```
1 ##### LOAD LIBRARY AND DEFINE CORE SETTINGS #####
2 #> @
3 #> @
4 #> @
5 ## Clear memory
6 rm(list = ls())
7
8 ## Load libraries
9 library(apollo)
10
11 ## Initialise code
12 apolloInitModel()
13
14 ## Set core controls
15 apollo_control = list(
16   modeChoice = "New_modeChoice_RP_base.mode",
17   modeDescr = "Simple MNL model on mode choice RP data",
18   indivID = "ID",
19   outputDirectory = "output"
20 )
```

# First model in Apollo

## View with all sections collapsed

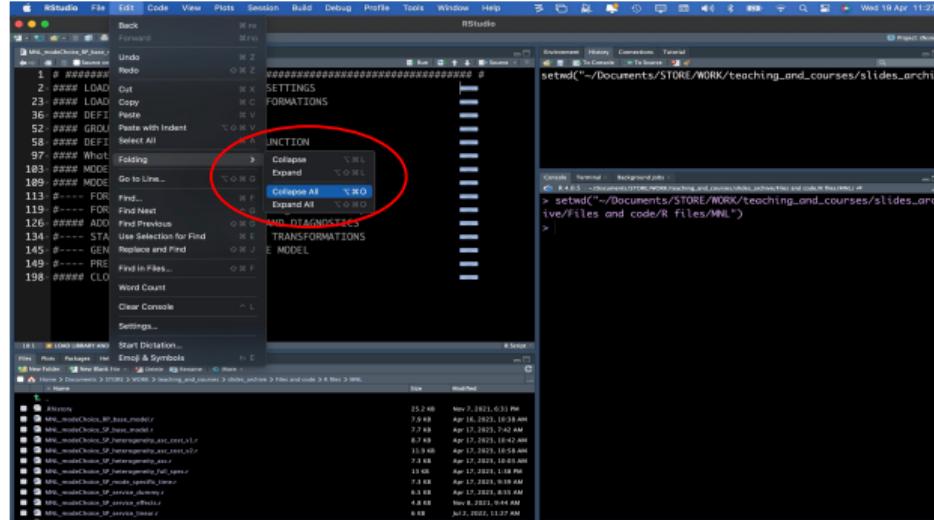

The screenshot shows the RStudio interface with the following components:

- Code Editor:** Displays the `MNL_modelChoice_MN_Java_model.R` file. The code is a series of comments (#) followed by numbers (1, 2, 3, etc.) and descriptions of the model's structure. It includes sections for library loading, data definition, parameter definition, model definition, estimation, outputs, and file writing.
- Console:** Shows the command `setwd("~/Documents/STORE/WORK/teaching_and_courses/slides_archive/files_and_code/R files and code/MNL")` being run.
- File Explorer:** Shows a directory tree under "Home".
- File List:** Shows a list of files with their sizes and last modified dates.

# First model in Apollo

Also possible via menu

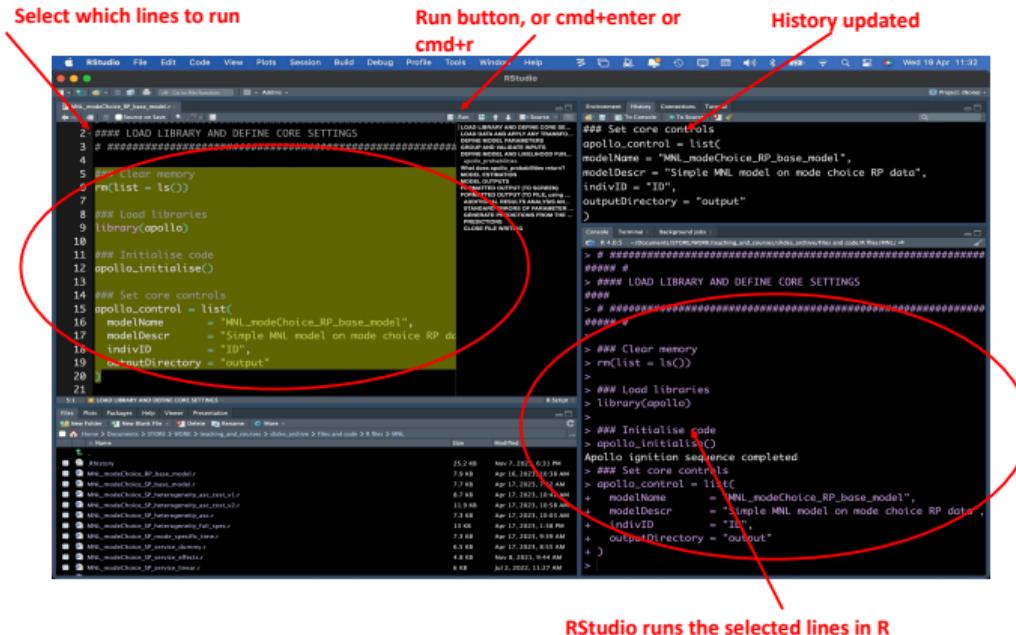

# First model in *Apollo*

**Document outline is useful (sections/functions)**

# First model in *Apollo*

## Running our first few lines (not whole script!)

# First model in *Apollo*

## What have we just done?

- Working directory is set so that R can find the files we're working with
- Then we cleared the memory from objects we might have loaded previously
- We loaded the *Apollo* package
- `apollo_initialise` removes attachments and closes any file writing that is still open
- Next have a number of important settings

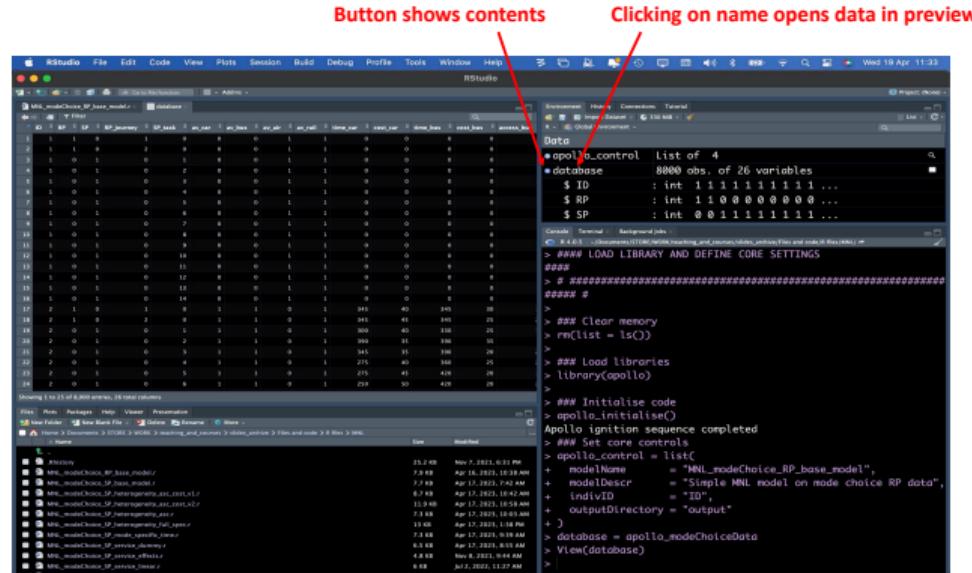

```
apollo_control = list(  
  modelName      = "MNL_modeChoice_RP_base_model",  
  modelDescr     = "Simple MNL model on mode choice RP data",  
  indivID        = "ID",  
  outputDirectory = "output"  
)
```

# First model in *Apollo*

## Loading the data: from the package in this case

# First model in *Apollo*

**Can see details of data**

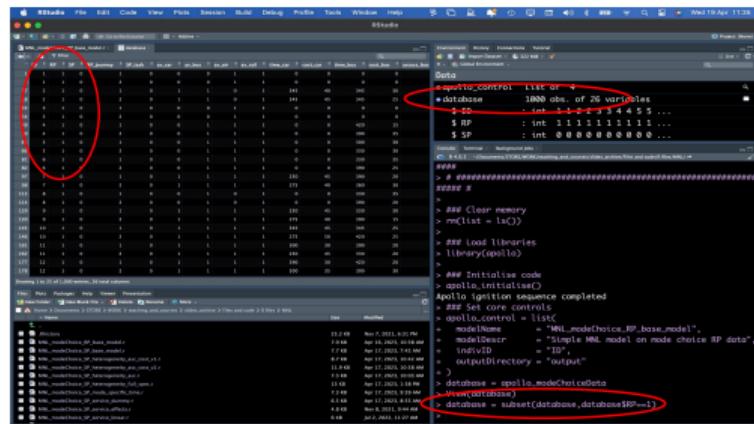

# First model in Apollo

## Uses RP data only (two choice observations per person)

- This uses the subset of database where the RP colum has a value of 1  
( $\text{==}$  is a boolean operator, equals 1 if true, 0 if false)

```
database = subset(database, database$RP==1)
```

The screenshot shows an RStudio interface with a code editor and a console window. The code editor contains the line of R code: `database = subset(database, database$RP==1)`. The console window shows the output of the command, which includes the creation of a new database object and the subset selection. A red circle highlights the command in the code editor, and another red circle highlights the output in the console.

```
##> #> database <- subset(database, database$RP==1)
```

```
##> #> database <- List of 4
##> #>   $ database: List of 26 variables
##> #>     $ ID    : int 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26
##> #>     $ RP   : int 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1
##> #>     $ SP   : int 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
##> #>
##> #>   $ modelHome: "MNL_modelChoice_RP_base.model"
##> #>   $ modelID  : "MNL"
##> #>   $ individualID: "ID"
##> #>   $ outputDirectory: "output"
##> #>
##> #> database <- apollo_modelChoiceData
##> #> database <- database
##> #> database <- subset(database, database$RP==1)
```

# First model in Apollo

## Defining parameters used by model

- Need to define starting values for all parameters

```
apollo_beta=c(asc_car = 0,  
             asc_bus = 0,  
             asc_air = 0,  
             asc_rail = 0,  
             b_tt = 0,  
             b_access = 0,  
             b_cost = 0)
```

- Possible to fix some parameters to their starting values, ASC for car in our model

```
apollo_fixed = c("asc_car")
```

- Now run those lines of code

# First model in *Apollo*

## Validating data and control

- ❑ Checks whether all settings have been set and whether ID column exists in data
- ❑ Also sorts the data by ID

```
apollo_inputs = apollo_validateInputs()
```

# First model in *Apollo*

## The apollo\_probabilities function

- Core part of the code
- Calculates and returns probabilities for individual choices
- Need to run function as a whole block
- Inputs are controlled by code (so user should not change them):
  - `apollo_beta`: parameter values used in evaluation of probabilities
  - `apollo_inputs`: all other model inputs (e.g. database, `apollo_control`)
  - functionality: mainly estimate or prediction, but also conditionals and output

# First model in *Apollo*

## Initialisation

- “Attach” data and parameters, meaning they can be referred to by name

```
apollo_attach(apollo_beta, apollo_inputs)
on.exit(apollo_detach(apollo_beta, apollo_inputs))
```

- Create a list called P which we will use for our probabilities
- Lists are a flexible R object , whose individual elements can be scalars, matrices, ...

```
P = list()
```

# First model in *Apollo*

## MNL model component

- *Apollo* contains a predefined function for MNL models

```
### List of utilities: these must use the same names as in mnl_settings, order is
  →irrelevant
V = list()
V[["car"]] = asc_car + b_tt * time_car + b_cost * cost_car
V[["bus"]] = asc_bus + b_tt * time_bus + b_access * access_bus + b_cost * cost_bus
V[["air"]] = asc_air + b_tt * time_air + b_access * access_air + b_cost * cost_air
V[["rail"]] = asc_rail + b_tt * time_rail + b_access * access_rail + b_cost * cost_rail

### Define settings for MNL model component
mnl_settings = list(
  alternatives = c(car=1, bus=2, air=3, rail=4),
  avail        = list(car=av_car, bus=av_bus, air=av_air, rail=av_rail),
  choiceVar    = choice,
  utilities    = V
)
```

# First model in *Apollo*

## Moving towards probabilities

- We now use the predefined function to calculate MNL probabilities

```
P[["model"]] = apollo_mnl(mnl_settings, functionality)
```

- At this point, this contains one row per observation, and possibly multiple columns if we use random draws (in mixture models)
- For models with multiple choices per person, we want to work with the sequence of choices per individual, so we take the product across choices, i.e.  $P_n = \prod_{t=1}^T P_{nt}$

```
P = apollo_panelProd(P, apollo_inputs, functionality)
```

- We finally use `apollo_prepareProb` to prepare the output of the `apollo_probabilities` function and return it

```
P = apollo_prepareProb(P, apollo_inputs, functionality)
```

# First model in *Apollo*

## The apollo\_probabilities function: illustration

- At the moment, our parameters are all at zero (the starting values)
- Let's see what happens if we use the model to calculate probabilities of the choices

```
> apollo_probabilities(apollo_beta, apollo_inputs, functionality="estimate")
[1] 0.2500000 0.1111111 0.2500000 0.1111111 0.1111111
[6] 0.1111111 0.0625000 0.2500000 0.0625000 0.0625000
[11] 0.0625000 0.0625000 0.0625000 0.2500000 0.1111111
[16] 0.1111111 0.1111111 0.0625000 0.1111111 0.1111111
```

- The values depend on what alternatives are available
- The first person only has air and rail available, so the probability for the actual choice (rail in both choices) is 0.5, and  $0.5 \cdot 0.5 = 0.25$

# First model in *Apollo*

## Running the model

- Read in all lines up to the end of the `apollo_probabilities` function
- Then we run the following line

```
model = apollo_estimate(apollo_beta, apollo_fixed, apollo_probabilities, apollo_inputs)
```

- Here, we just use the default settings, but user can change estimation routine, etc

# First model in Apollo

## Running the model: first part

- First runs some diagnostics, checking names of alternatives match utilities, etc

```
Testing probability function (apollo_probabilities)
```

- Then presents some overview of choices

|                                  | Overview of choices for MNL model component: |        |        |        |
|----------------------------------|--|--------|--------|--------|
|                                  | car  | bus    | air    | rail   |
| Times available                  | 778.00                                       | 902.00 | 752.00 | 874.00 |
| Times chosen                     | 332.00                                       | 126.00 | 215.00 | 327.00 |

# First model in Apollo

## Running the model: actual estimation

- LL starts at value obtained with our starting values, then improves until convergence
- We minimise the negative of the LL, which is the same as maximising the LL

```
Pre-processing likelihood function ...
Testing influence of parameters
Starting main estimation
BGW using analytic model derivatives supplied by caller ...

Iterates will be written to:
output/MNL_modeChoice_RP_base_model_iterations.csv      it      nf      F

## Functions for output

- ❑ Output to screen (`apollo_modelOutput`) and file (`apollo_saveOutput`)
- ❑ Need a model object as input
- ❑ Both can take a list of settings, or just use defaults

# First model in *Apollo*

# First model in Apollo

## Covariance and correlation matrix (in saved output)

- Look out for any really high correlations between coefficients (say above 0.95)
- Would imply two parameters explaining the same thing (opposite if negative)

| Robust correlation matrix: |          |          |          |           |           |          |

# First model in Apollo

## MRS calculations for RP model

- ❑ Use apollo\_deltaMethod to compute the VTT and its standard errors, and difference between in vehicle and access time
- ❑ Calculate VTT both in base units (£ and minutes) as well as in £ and hours
- ❑ Also instruct R to dump this output to a text file

```
> apollo_sink()
> apollo_deltaMethod(model,
+                      deltaMethod_settings = list(
+                        expression=c(VTT_per_minute="b_tt/b_cost",
+                                     VTT_per_hour="60*b_tt/b_cost",
+                                     b_tt_vs_access="b_tt-b_access"
+ )))

Running Delta method computation for user-defined function:

      Expression   Value Robust s.e. Rob t-ratio (0)
VTT_per_minute  0.1966     0.0406      4.84
  VTT_per_hour 11.7949     2.4366      4.84
b_tt_vs_access  0.0014     0.0060      0.24
```

# Changes to a model: adding explanatory variables

# Changes to a model: adding explanatory variables

## Good practice

---

- Rule 1: whenever you change a model specification, save it as a new file!
- Rule 2: use the same text for the modelName as for the filename, to ensure output files have the same name as the model!

# Changes to a model: adding explanatory variables

## Moving to SP data

- We will now make use of the larger SP sample
- Change file name to **MNL\_modeChoice\_SP\_base\_model.r**
- Update modelName in apollo\_control
- Think about what you need to change to use the SP part of the sample

# Changes to a model: adding explanatory variables

## Outputs of model estimation

- More data, and thus also more negative LL and smaller standard errors

|                                    |          |            |           |            |               |

# Changes to a model: adding explanatory variables

## MRS calculations for SP model

- MRS very similar to RP results

```
> apollo_deltaMethod(model,
+                      deltaMethod_settings = list(
+                        expression=c(VTT_per_minute="b_tt/b_cost",
+                                     VTT_per_hour="60*b_tt/b_cost",
+                                     b_tt_vs_access="b_tt-b_access",
+                                     )))
Running Delta method computation for user-defined function:

  Expression   Value Robust s.e. Rob t-ratio (0)
VTT_per_minute 0.1889    0.0100      18.83
VTT_per_hour 11.3360    0.6019      18.83
b_tt_vs_access 0.0083    0.0025      3.26
```

# Changes to a model: adding explanatory variables

## Instructions

- Include categorical service quality for air and rail (1=no frills, 2=wifi, 3=food)
- Three levels of difficulty:
  - level 1 treat as a continuous (linear) attribute, same as e.g. travel time
  - level 2 treat as categorical, using dummy coding (remember normalisation, and convince yourself that the choice of base is arbitrary)
    - can create a new variable for each level before apollo\_probabilities  
(e.g. database\$service\_air\_wifi=(database\$service\_air==2))
    - or use the code directly inside the utilities  
(e.g. ...+beta\_wifi\*(service\_air==2)+...)
  - level 3 contrast with effects coding (base level  $\beta$  is negative sum of others)
- Can base these on **MNL\_modeChoice\_SP\_base\_model.r**
  - BUT CHANGE THE NAME, and add to the bit on WTP calculation at the end

# Changes to a model: adding explanatory variables

## Results (try out apollo\_combineResults())

# Changes to a model: adding explanatory variables

## WTP from linear model

- Service quality is a desirable attribute, so we can change the sign in the WTP calculations (but of course we could just do this manually)
- Small change in VTT, but linear assumption for service quality clearly not reasonable

```
> apollo_deltaMethod(model,
+                      deltaMethod_settings = list(
+                        expression=c(VTT_per_minute="b_tt/b_cost",
+                                     VTT_per_hour="60*b_tt/b_cost",
+                                     WTP_wifi="-b_service/b_cost",
+                                     WTP_food="-2*b_service/b_cost"
+ )))

Running Delta method computation for user-defined function:

      Expression   Value Robust s.e. Rob t-ratio (0)
VTT_per_minute 0.1916    0.0099     19.26
VTT_per_hour 11.4931    0.5968     19.26
WTP_wifi       3.2902    0.4421      7.44
WTP_food       6.5803    0.8843      7.44
```

# Changes to a model: adding explanatory variables

## WTP from dummy coded model

- Small changes for VTT, but we now see that Wifi is better than food
- With categorical attributes, can only work in differences

```
> apollo_deltaMethod(model,
+                      deltaMethod_settings = list(
+                        expression=c(VTT_per_minute="b_tt/b_cost",
+                                    VTT_per_hour="60*b_tt/b_cost",
+                                    WTP_wifi="-(b_wifi-b_no_frills)/b_cost",
+                                    WTP_food="-(b_food-b_no_frills)/b_cost"
+                        )))

The expression WTP_wifi includes parameters that were fixed in estimation: b_no_frills
These have been replaced by their fixed values, giving: -(b_wifi-0)/b_cost
The expression WTP_food includes parameters that were fixed in estimation: b_no_frills
These have been replaced by their fixed values, giving: -(b_food-0)/b_cost

Running Delta method computation for user-defined function:

  Expression   Value Robust s.e. Rob t-ratio (0)
VTT_per_minute 0.2053      0.0095      21.56
VTT_per_hour 12.3200      0.5714      21.56
WTP_wifi 16.2084      1.0033      16.15
WTP_food  7.0127      0.8949       7.84
```

# Changes to a model: adding explanatory variables

## Dummy vs effects coding

- Only asc\_air, asc\_rail, b\_wifi and b\_food change
- But all differences remain the same
- The change in ASC is what has caused confusion in the literature
  - But only differences in utility matter, so there is no confounding
  - And the dummy coded one has a clear base (as opposed to an unweighted average)

|                    | dummy   | effects |
|--------------------|---------|---------|
| asc_car            | 0       | 0       |
| asc_bus            | -2.0429 | -2.0429 |
| asc_air            | -0.5878 | -0.1334 |
| asc_rail           | -0.862  | -0.4076 |
| b_tt               | -0.0121 | -0.0121 |
| b_access           | -0.0199 | -0.0199 |
| b_cost             | -0.0587 | -0.0587 |
| <b>b_no_frills</b> | 0       | -0.4544 |
| b_wifi             | 0.9515  | 0.4971  |
| b_food             | 0.4117  | -0.0427 |
| b_food-b_no_frills | 0.4117  | 0.4117  |
| b_wifi-b_no_frills | 0.9515  | 0.9515  |
| b_wifi-b_food      | 0.5398  | 0.5398  |

# Changes to a model: adding explanatory variables

## Likelihood ratio test: linear vs base

- The model with linear service quality is the more general model
- If service quality goes to zero, the model collapses to our base model

```
> apollo_lrTest("MNL_modeChoice_SP_base_model",model)
                                         LL  par
MNL_modeChoice_SP_base_model      -5788.59    6
MNL_modeChoice_SP_service_linear -5761.74    7
Difference                      26.85    1

Likelihood ratio test-value:   53.7
Degrees of freedom:           1
Likelihood ratio test p-value: 2.336e-13
```

- Improvement is large enough to allow us to reject  $H_0$  that the models are equivalent
- This function can also be run for two previously saved models (rather than one in memory against a saved one)

# Changes to a model: adding explanatory variables

## Likelihood ratio test: dummy vs base

- Can also compare the dummy coded model to the model without service quality
- If both service quality parameters go to zero, the model collapses to our base model

```
> apollo_lrTest("MNL_modeChoice_SP_base_model", model)
          LL  par
MNL_modeChoice_SP_base_model -5788.59   6
MNL_modeChoice_SP_service_dummy -5615.39   8
Difference                  173.20   2

Likelihood ratio test-value: 346.4
Degrees of freedom:         2
Likelihood ratio test p-value: 6.028e-76
```

- Improvement is large enough to allow us to reject  $H_0$  that the models are equivalent

# Changes to a model: adding explanatory variables

## Ben-Akiva & Swait test: dummy vs linear

- Compare model with dummy coding and model using linear service quality

```
> apollo_basTest("MNL_modeChoice_SP_service_linear", model)
          LL0      LL  par adj.rho2
MNL_modeChoice_SP_service_linear -8196.02 -5761.74 7  0.2962
MNL_modeChoice_SP_service_dummy   -8196.02 -5615.39 8  0.3139
Difference                      0.00  146.35  1  0.0177

p-value for Ben-Akiva & Swait test: 1.404e-65
```

- Can reject  $H_0$  that the models are equivalent

# Mode specific time coefficients

$$\sigma_x = \sqrt{V} = \frac{1}{\pi} \int f^2(x) dx$$

$$\frac{1}{\sqrt{1 - k^2 \sin^2(x)}} = 1 + \sum_{n=1}^{\infty} \sum_{x=0}^{\infty} P_n$$

# Mode specific time coefficients

## Your next task

- We already account for differences in VTT between in vehicle time and access time
- But a minute spent on a bus is not the same as a minute spent on a train
- Two levels of difficulty:
  - level 1 use mode specific coefficients for in vehicle time
  - level 2 model fit comparisons against base model, and statistical tests for differences in time sensitivities across modes
- You can base these on the model with dummy coded service quality, i.e.  
`MNL_modeChoice_SP_service_dummy.r`

# Mode specific time coefficients

## Output with mode specific time coefficients

- Solution in `MNL_modeChoice_SP_mode_specific_time.r`
- Negative time sensitivities for all four modes

| LL(final)   | : -5598.9 |            |           |            |               |

# Mode specific time coefficients

## Model fit comparison

- Smaller improvement over model with generic time coefficients
- But large enough to reject  $H_0$  of no differences

```
> apollo_lrTest("MNL_modeChoice_SP_service_dummy", model)
                                         LL par
MNL_modeChoice_SP_service_dummy      -5615.39   8
MNL_modeChoice_SP_mode_specific_time -5598.90   11
Difference                           16.49    3

Likelihood ratio test-value: 32.98
Degrees of freedom: 3
Likelihood ratio test p-value: 3.252e-07
```

# Mode specific time coefficients

## WTP implications

- Big differences visible across modes
- Can also look at t-ratio for those differences

```
> apollo_deltaMethod(model,
+                      deltaMethod_settings = list(
+                        expression=c(VTT_car="60*b_tt_car/b_cost",
+                                    VTT_bus="60*b_tt_bus/b_cost",
+                                    VTT_air="60*b_tt_air/b_cost",
+                                    VTT_rail="60*b_tt_rail/b_cost",
+                                    TT_car_vs_rail="b_tt_car-b_tt_rail",
+                                    VTT_car_vs_rail="60*((b_tt_car-b_tt_rail)/b_cost)"
+                      )))
Running Delta method computation for user-defined function:

  Expression   Value Robust s.e. Rob t-ratio (0)

  VTT_car_vs_rail  5.3482   1.7717       3.02
```

# WTP space

# WTP space

## Your next task

- Take `MNL_modeChoice_SP_mode_specific_time.r` and write this model in WTP space (keeping ASCs in preference space)
  - remember: moving to WTP space simply involves multiplying some of the non-cost components by the cost coefficient
  - think about how to code this efficiently

# WTP space

## Results for WTP space model

- Solution in `MNL_modeChoice_SP_WTP_space.r`
